

Angle Resolved Photoemission Spectroscopy

From fundamentals to the heart of condensed matter

6-7 FEBRERO, 2023

Lecture #3 : ARPES Studies of Quantum Materials

6-7 FEBRERO, 2023

Consider an ARPES experiment being conducting with an electron analyzer resolution of $\Delta E = 10$ meV and an photon bandwidth of $\Delta E = 2$ meV

What is the closest value of the **TOTAL** “effective” energy broadening in the experiment?

- A. 10 meV
- B. 11 meV
- C. 12 meV
- D. 13 meV

Consider an ARPES experiment being conducting with an electron analyzer resolution of $\Delta E = 10$ meV and an photon bandwidth of $\Delta E = 2$ meV

What is the closest value of the **TOTAL** “effective” energy broadening in the experiment?

- A. 10 meV
- B. 11 meV
- C. 12 meV
- D. 13 meV

In your ARPES experiment of a given material, you see a sharp “kink” in the quasiparticle band dispersion, which is a clear signature of some electron-boson interaction.

What information **cannot** be directly obtained from the analysis of your experimental data?

- A. The energy of the boson
- B. The strength of the electron-boson interaction
- C. What kind of boson it is (i.e. phonon, magnon, etc...)
- D. None of A, B, and C can be obtained from the data
- E. All of A, B, and C can be obtained from the data

In your ARPES experiment of a given material, you see a sharp “kink” in the quasiparticle band dispersion, which is a clear signature of some electron-boson interaction.

- B. The strength of the electron-boson interaction
- C. What kind of boson it is (i.e. phonon, magnon, etc...)
- D. None of A, B, and C can be obtained from the data
- E. All of A, B, and C can be obtained from the data

Which of the following material properties would be directly observable using ARPES?

- | | |
|--|---------------------|
| 1. The exciton binding energy in a semiconductor | A. 2 & 4 |
| 2. The strength of electron-phonon interactions in a metal | B. 1, 3, 4, & 5 |
| 3. The magnon (spin-wave) dispersion in an antiferromagnet | C. 2, 3, 4, & 5 |
| 4. The interacting quasiparticle band structure | D. 3, 4, & 5 |
| 5. The electronic band structure as calculated by DFT | E. All of the above |

ARPES measurements need to take place in ultrahigh vacuum (10^{-10} torr or better). Which of the following is the **most important** factor which determines the level of vacuum needed to perform experiments?

- A. The scattering / absorption of photoelectrons traveling inside the chamber
- B. The operation of the electron analyzer
- C. The absorption of vacuum ultraviolet (VUV) photons used for photoemitting the electrons
- D. The scattering of electrons from adsorbed molecules at the sample's surface
- E. All of the above are equally important

Data Processing

New Materials

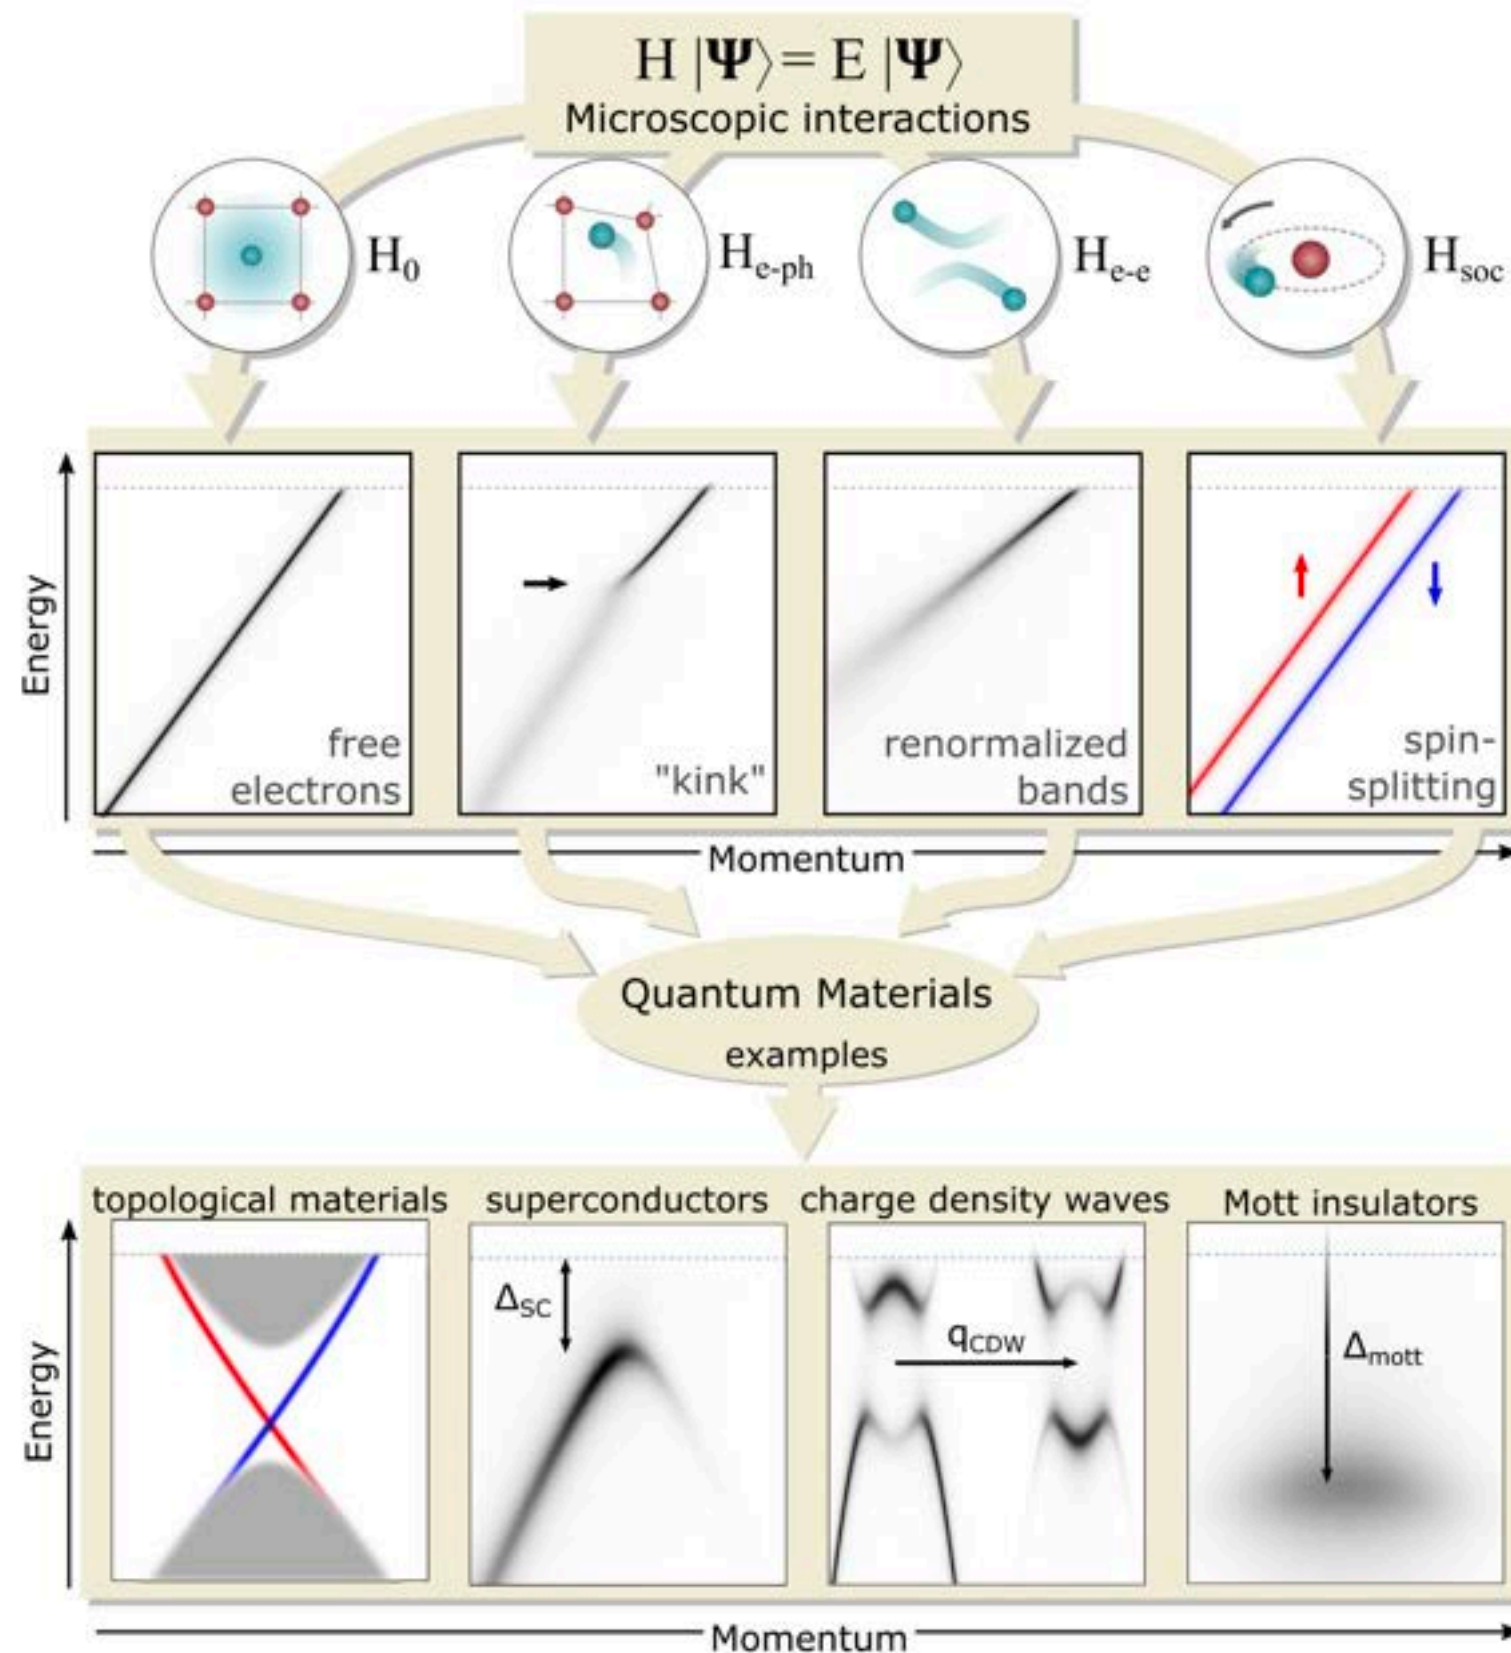

Scientific Questions

State-of-the-art Theory

Example #1 : High-Temperature Cuprate Superconductors

- Evolution from the parent Mott insulating state
- *d*-wave superconducting gap
- discovery of the pseudogap

Example #2 : Strain Engineering of Superconductivity

- “Fermi Surface Engineering” in strained Sr_2RuO_4
- The first strain-stabilized superconductor : RuO_2

Example #3 : Monolayer High-Tc Interfacial Superconductivity

- Pairing enhancement in $\text{FeSe} / \text{SrTiO}_3$
- Interfacial Electron-Phonon Coupling in $\text{FeSe} / \text{SrTiO}_3$

superconductivity : macroscopic quantum phenomena

quantum sensors

transition edge sensor

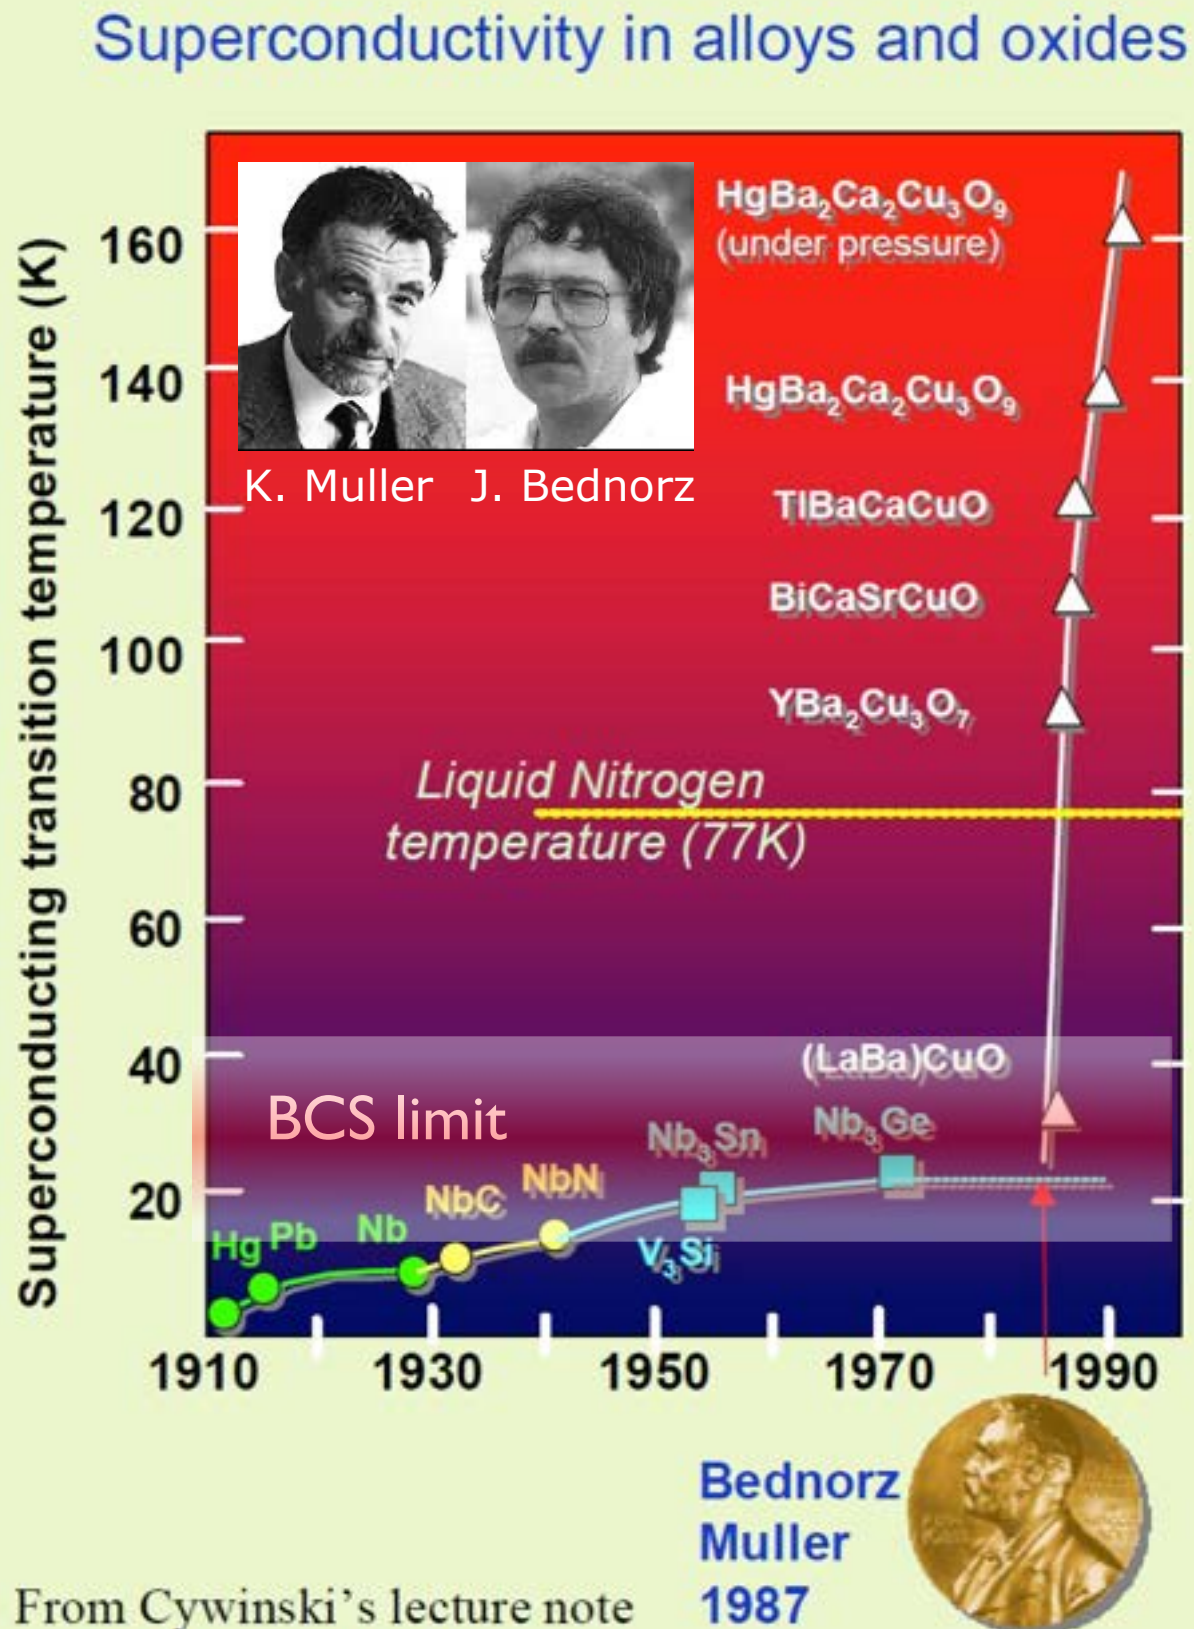

Superconducting Quantum Interference Device (SQUID)

quantum computing

High- T_c Cuprate Superconductors : The “Hydrogen Atom” of Quantum Materials

- Conventional “*independent electron*” band theory that works so well for materials like silicon fails completely for cuprates
- Jump-started research on the many-body physics (quantum materials) - “physics of the many”
- Motivated the discovery of many other families of “quantum materials”

Many-Body Interactions in Cuprates : Strong Correlations

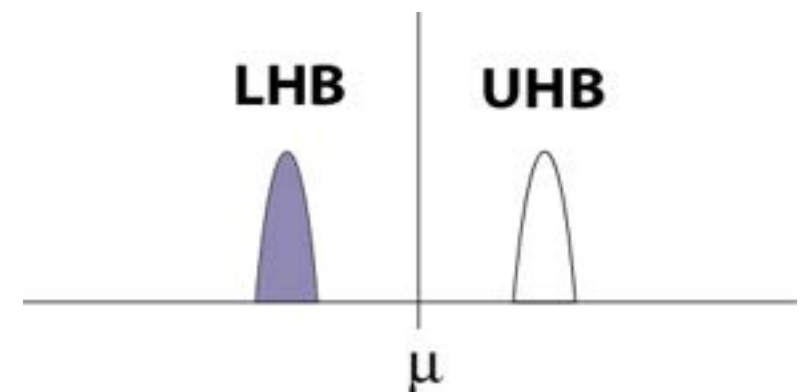

One-Electron Prediction :

Half-filled metal with ~ 3 eV bandwidth

Real Situation :

Mott insulator with ~ 2 eV gap

$$H\psi = E\psi \quad H = \sum_{i=1}^N \left(-\frac{\hbar^2}{2m} \nabla_i^2 - Ze^2 \sum_R \frac{1}{|ri - R|} \right) + \frac{1}{2} \sum_{i \neq j} \frac{e^2}{|ri - rj|}$$

independent electrons – indeed unreasonable approximation?

High- T_c is an extension of the long standing problem of insulating oxides – “Mott Insulators”

P.W. Anderson, 1987

$$\mathcal{H} = -t \sum_{i,\sigma} \left(c_{i\sigma}^\dagger c_{i+1\sigma} + h.c. \right) + U \sum_i n_{i\uparrow} n_{i\downarrow}$$

Source of the strong pairing attraction

?

The “hydrogen atom” model of strongly correlated electrons

John Hubbard

Courtesy of ZX Shen

Band Structure Predictions : Non-Interacting

Kinetic Energy Only

Mott Insulator : Magnetic Interactions

KE & Magnetism

$$t\text{-}J : \quad \mathcal{H} = -t \sum_{\langle ij \rangle, \sigma} (c_{i\sigma}^\dagger c_{j\sigma} + \text{h.c.}) + J \sum_{\langle ij \rangle, \sigma} (\mathbf{S}_i \cdot \mathbf{S}_j - \frac{n_i n_j}{4})$$

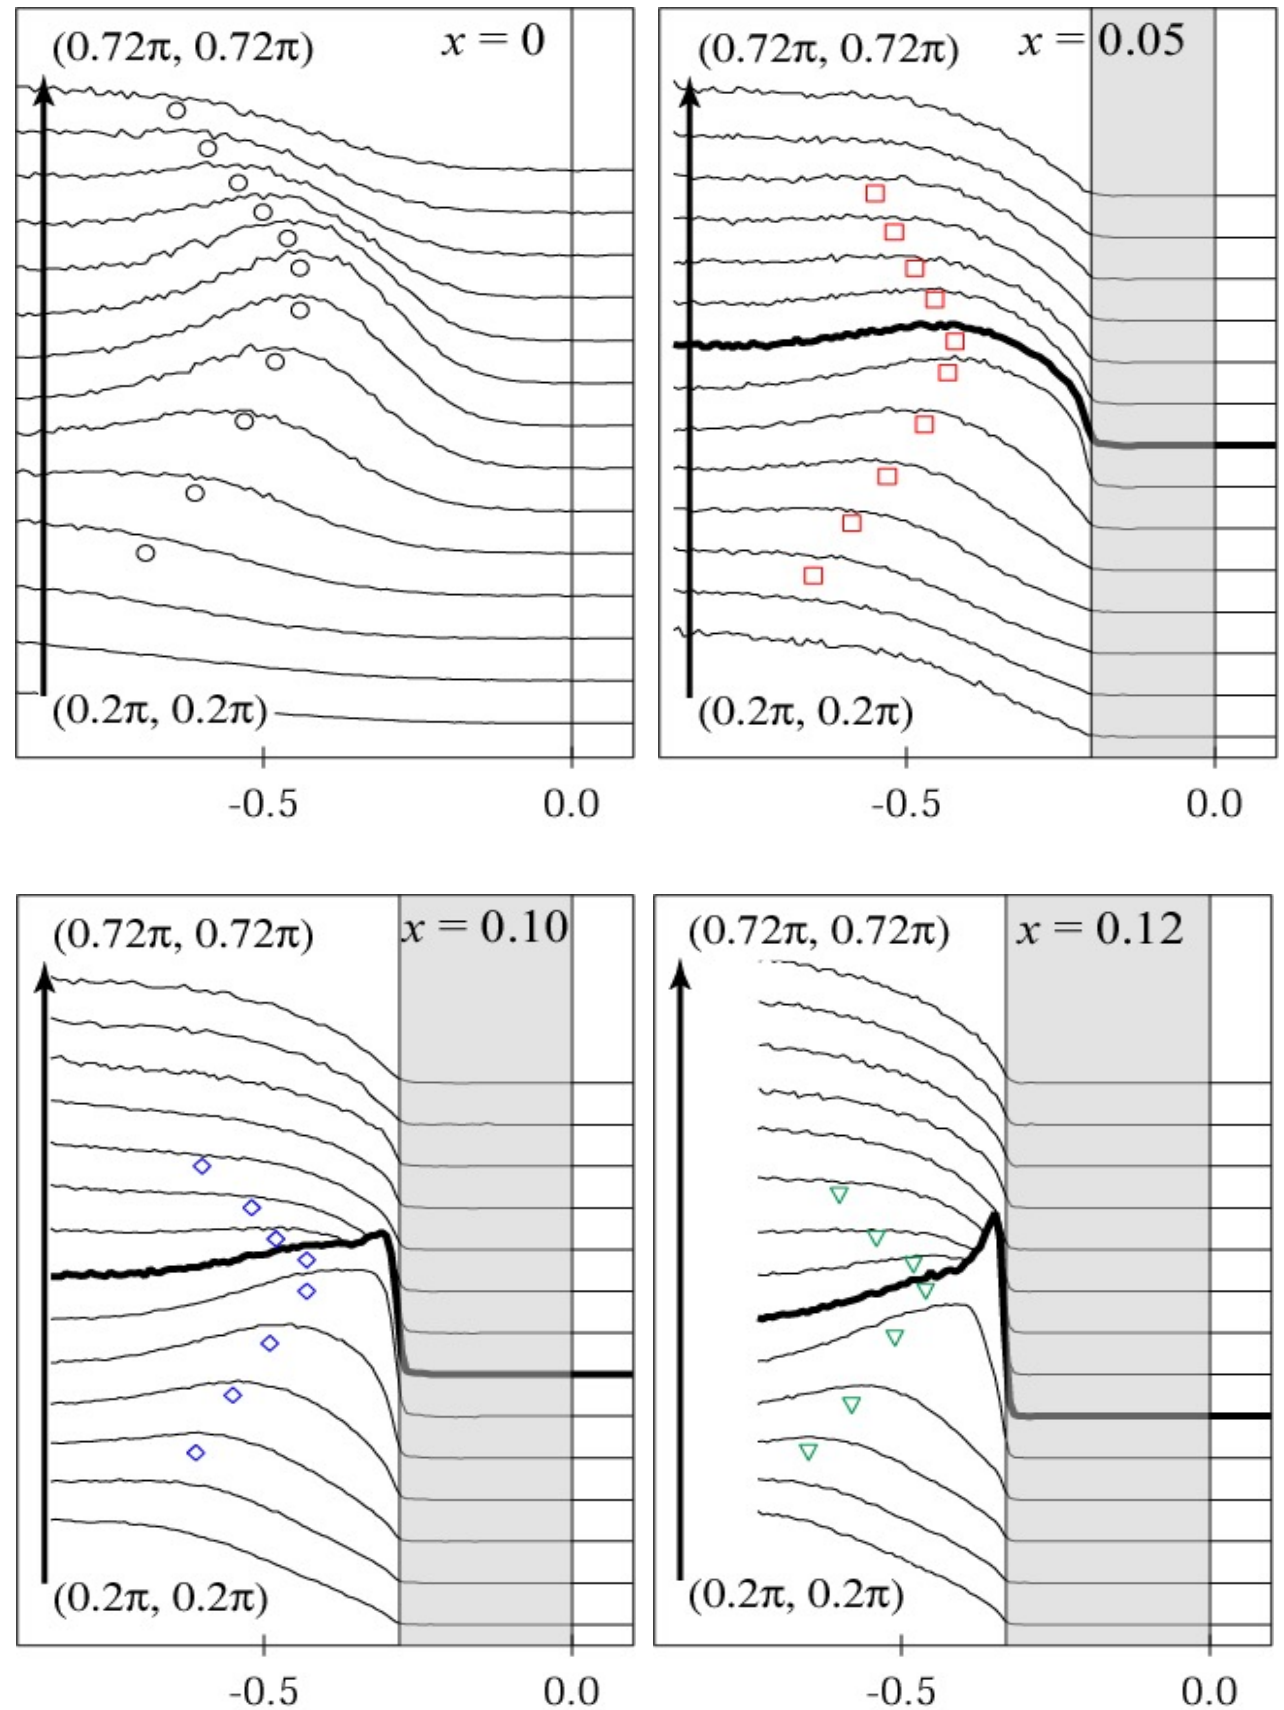

A Single Hole in the Mott Insulator

Chemical Potential Shift : $O2p_{\pi}$ & $O2p_z$

Evolution of Low Energy States with Doping

Ruthenate properties are highly tunable with structural changes

RuO₆ octahedra

Ru⁴⁺ : 4d⁴

Compound	Dimensionality	Octahedral Connectivity	Properties
Sr ₂ RuO ₄	2D	CORNER	Exotic SC
Ca ₂ RuO ₄	2D	CORNER	AF Mott Insulator
CaRuO ₃	3D	CORNER	heavy FL
SrRuO ₃	3D	CORNER	FM Metal
RuO ₂	3D	EDGE & CORNER	Metal

ground states can be tuned from metal, AF insulator, FM metal, exotic SC, simply by changing connectivity of RuO₆ octahedra (without doping)

- various experiments (μ SR, Kerr rotation) point towards broken time-reversal symmetry
- simple chiral *p*-wave, spin-triplet model called into question by recent experiments
- order parameter is unconventional, but precise nature still up for debate

WANTED : clean knobs to control SC in Sr_2RuO_4

traditional approaches like doping and chemical substitution cannot be applied to studying superconductivity of Sr_2RuO_4

uniaxial or epitaxial (biaxial) strain is a clean alternative

D.A. Bonn, Nature Phys. (2007)

- HTSCs (cuprates, Fe-SC) require doping at the level of 10% to realize SC
- SC is robust at the level of 100,000s of ppm's!
- superconducting coherence lengths ~ 1 nm

A.P. Mackenzie et. al, *Phys. Rev. Lett.* **80**, 161 (1998)

- Sr_2RuO_4 is the most disorder-sensitive SC known
- tens to hundreds of ppm's of impurities kills SC
- superconducting coherence lengths ~ 0.1 microns

- strains on the order of a couple percent can be applied
- does not introduce substantial disorder
- can also be implemented in device structures

in-plane uniaxial strain significantly increases T_c in Sr_2RuO_4

enhancements in T_c may be tied to proximity of van Hove singularity to E_F ; proposed that "Lifshitz transition" likely gives rise to the sharp peak in T_c with strain.

How does electronic structure evolve with epitaxial strain?

epitaxial strain as a tuning parameter in quantum material heterostructures

- clean tuning parameter (unlike chemical pressure)
- enables most spectroscopies & probes (unlike hydrostatic pressure)
- much larger strains than possible in bulk crystals (and different symmetries), ~3%
- scalable and enables device fabrication (e.g. strained silicon MOSFETs)

molecular beam epitaxy (MBE)

*“atomic spray
painting”*

advantages of MBE

- sub-monolayer control of atomic layers
- can create nearly perfect atomic interfaces, heterostructures, or metastable structures not possible in bulk
- can synthesize materials of extremely high purity
- used for synthesizing laser diodes, LEDs, photovoltaics, etc....

molecular beam epitaxy (MBE)

integrated ARPES & MBE system

Can tensile strain push the van Hove singularity closer to E_F ?

Bulat
Burganov

Carolina
Adamo

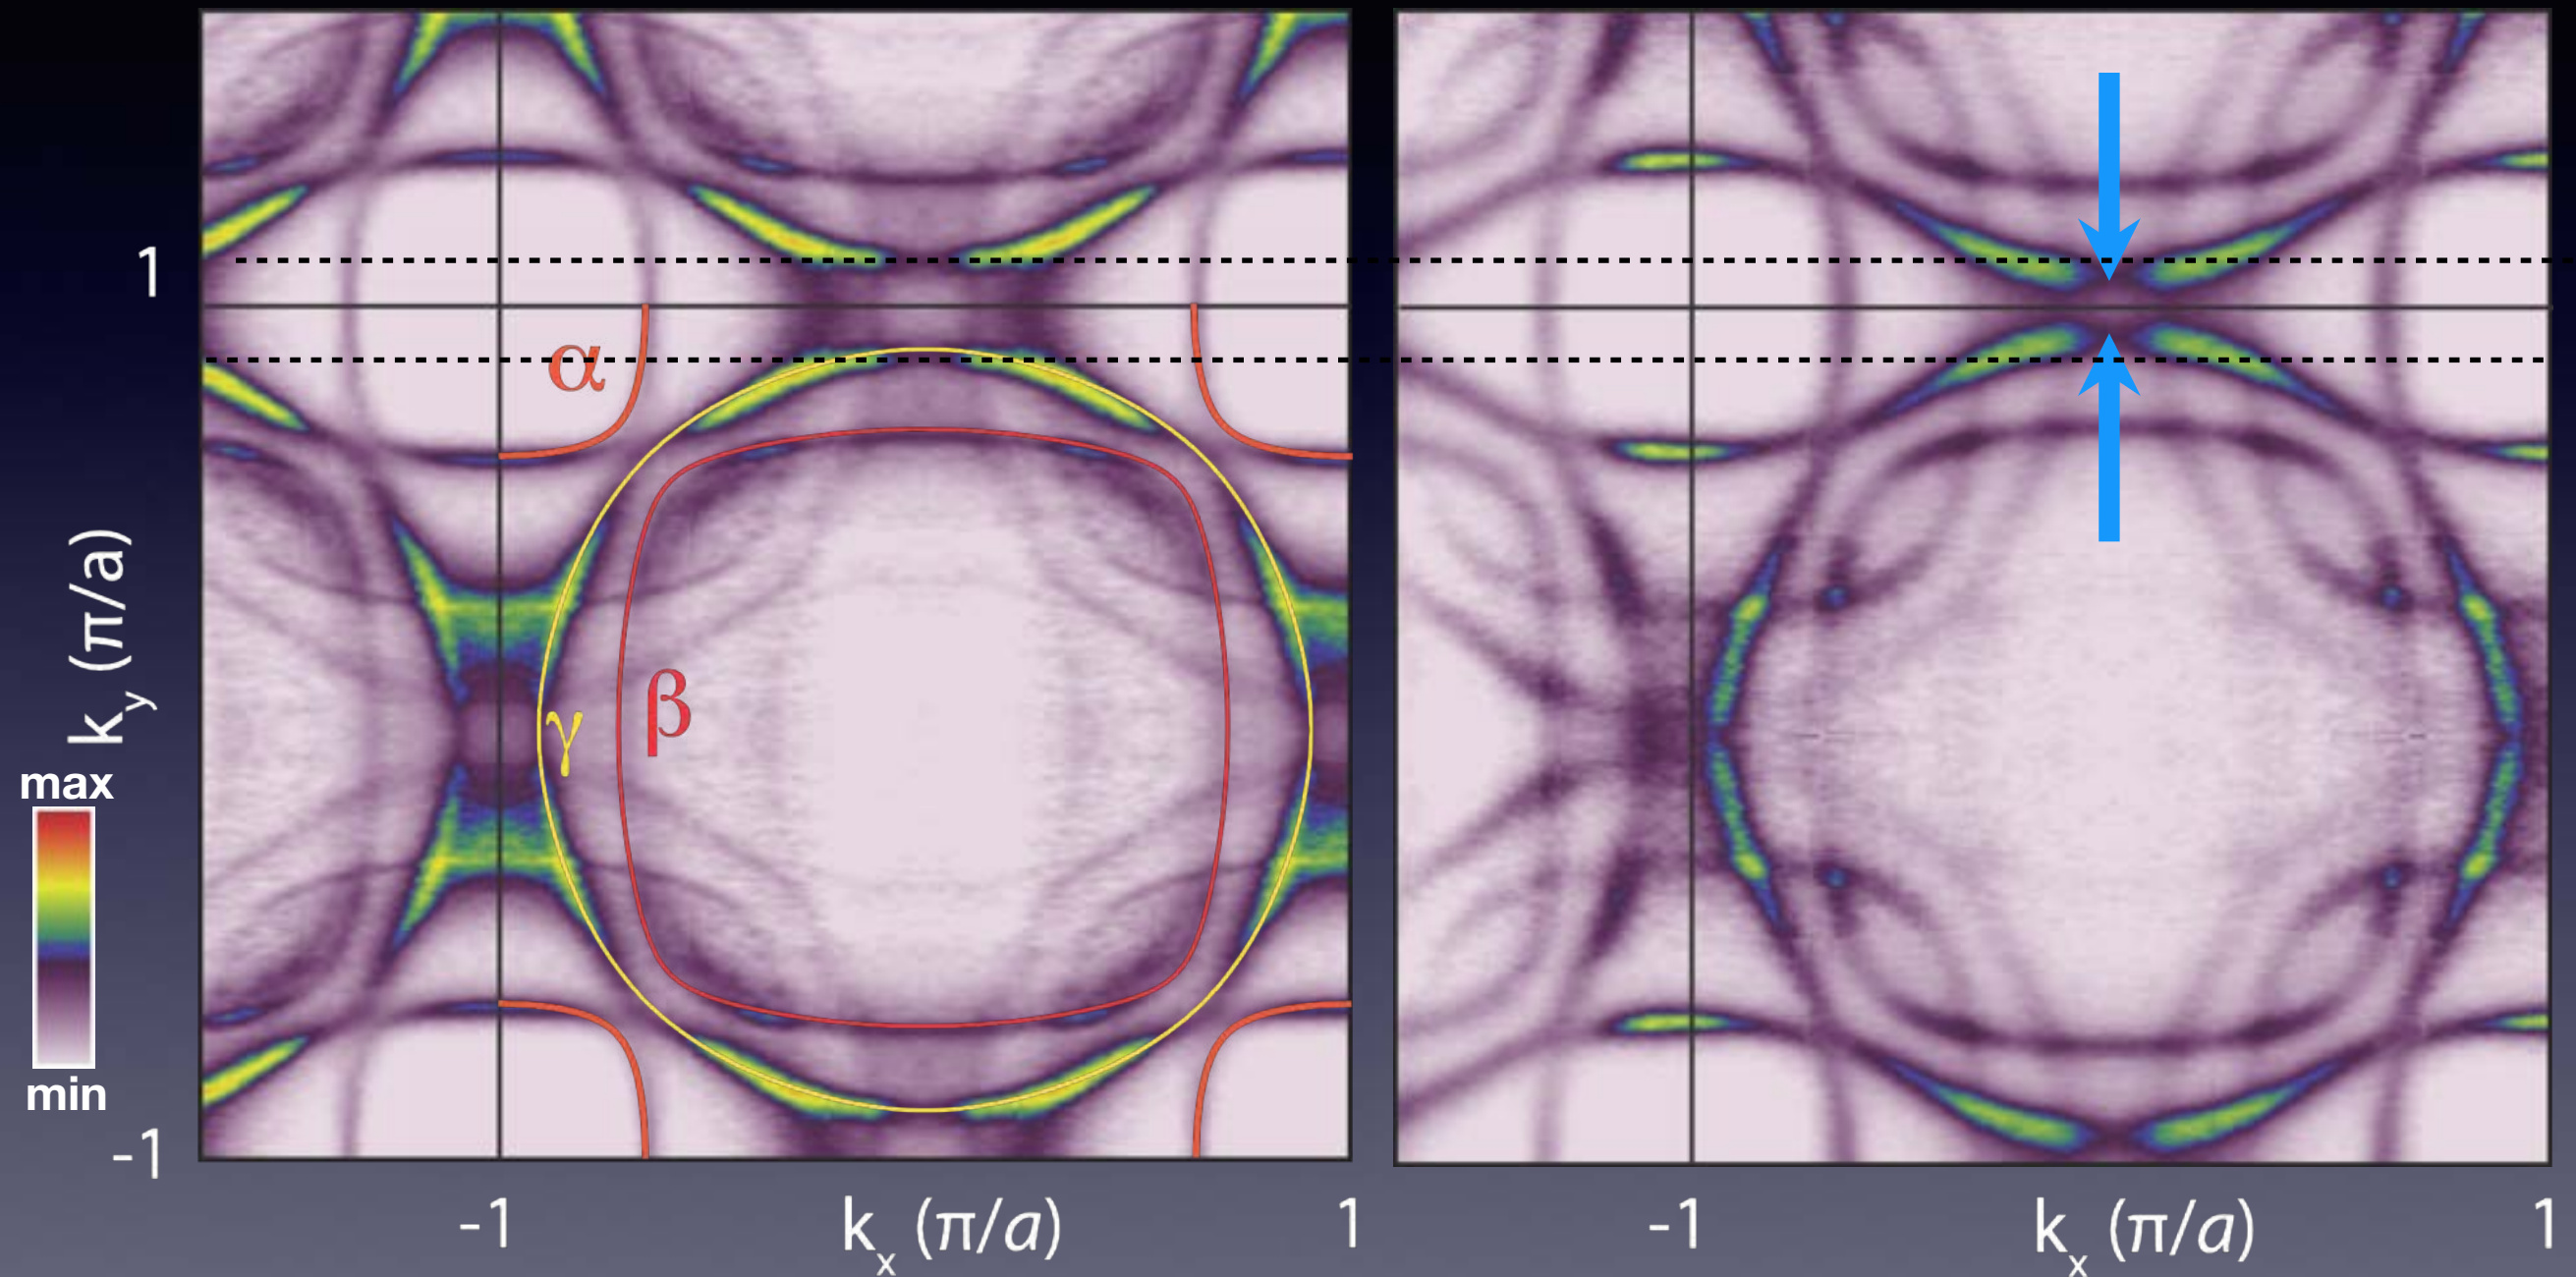

B. Burganov, et al., *Phys. Rev. Lett.* **116**, 197003
single crystal from A.P. Mackenzie

Can tensile strain push the van Hove singularity closer to E_F ?

Sr_2RuO_4 single crystal

Sr_2RuO_4 on SrTiO_3 (+0.9%)

Epitaxial strain to enhance superconductivity in Sr_2RuO_4 ?

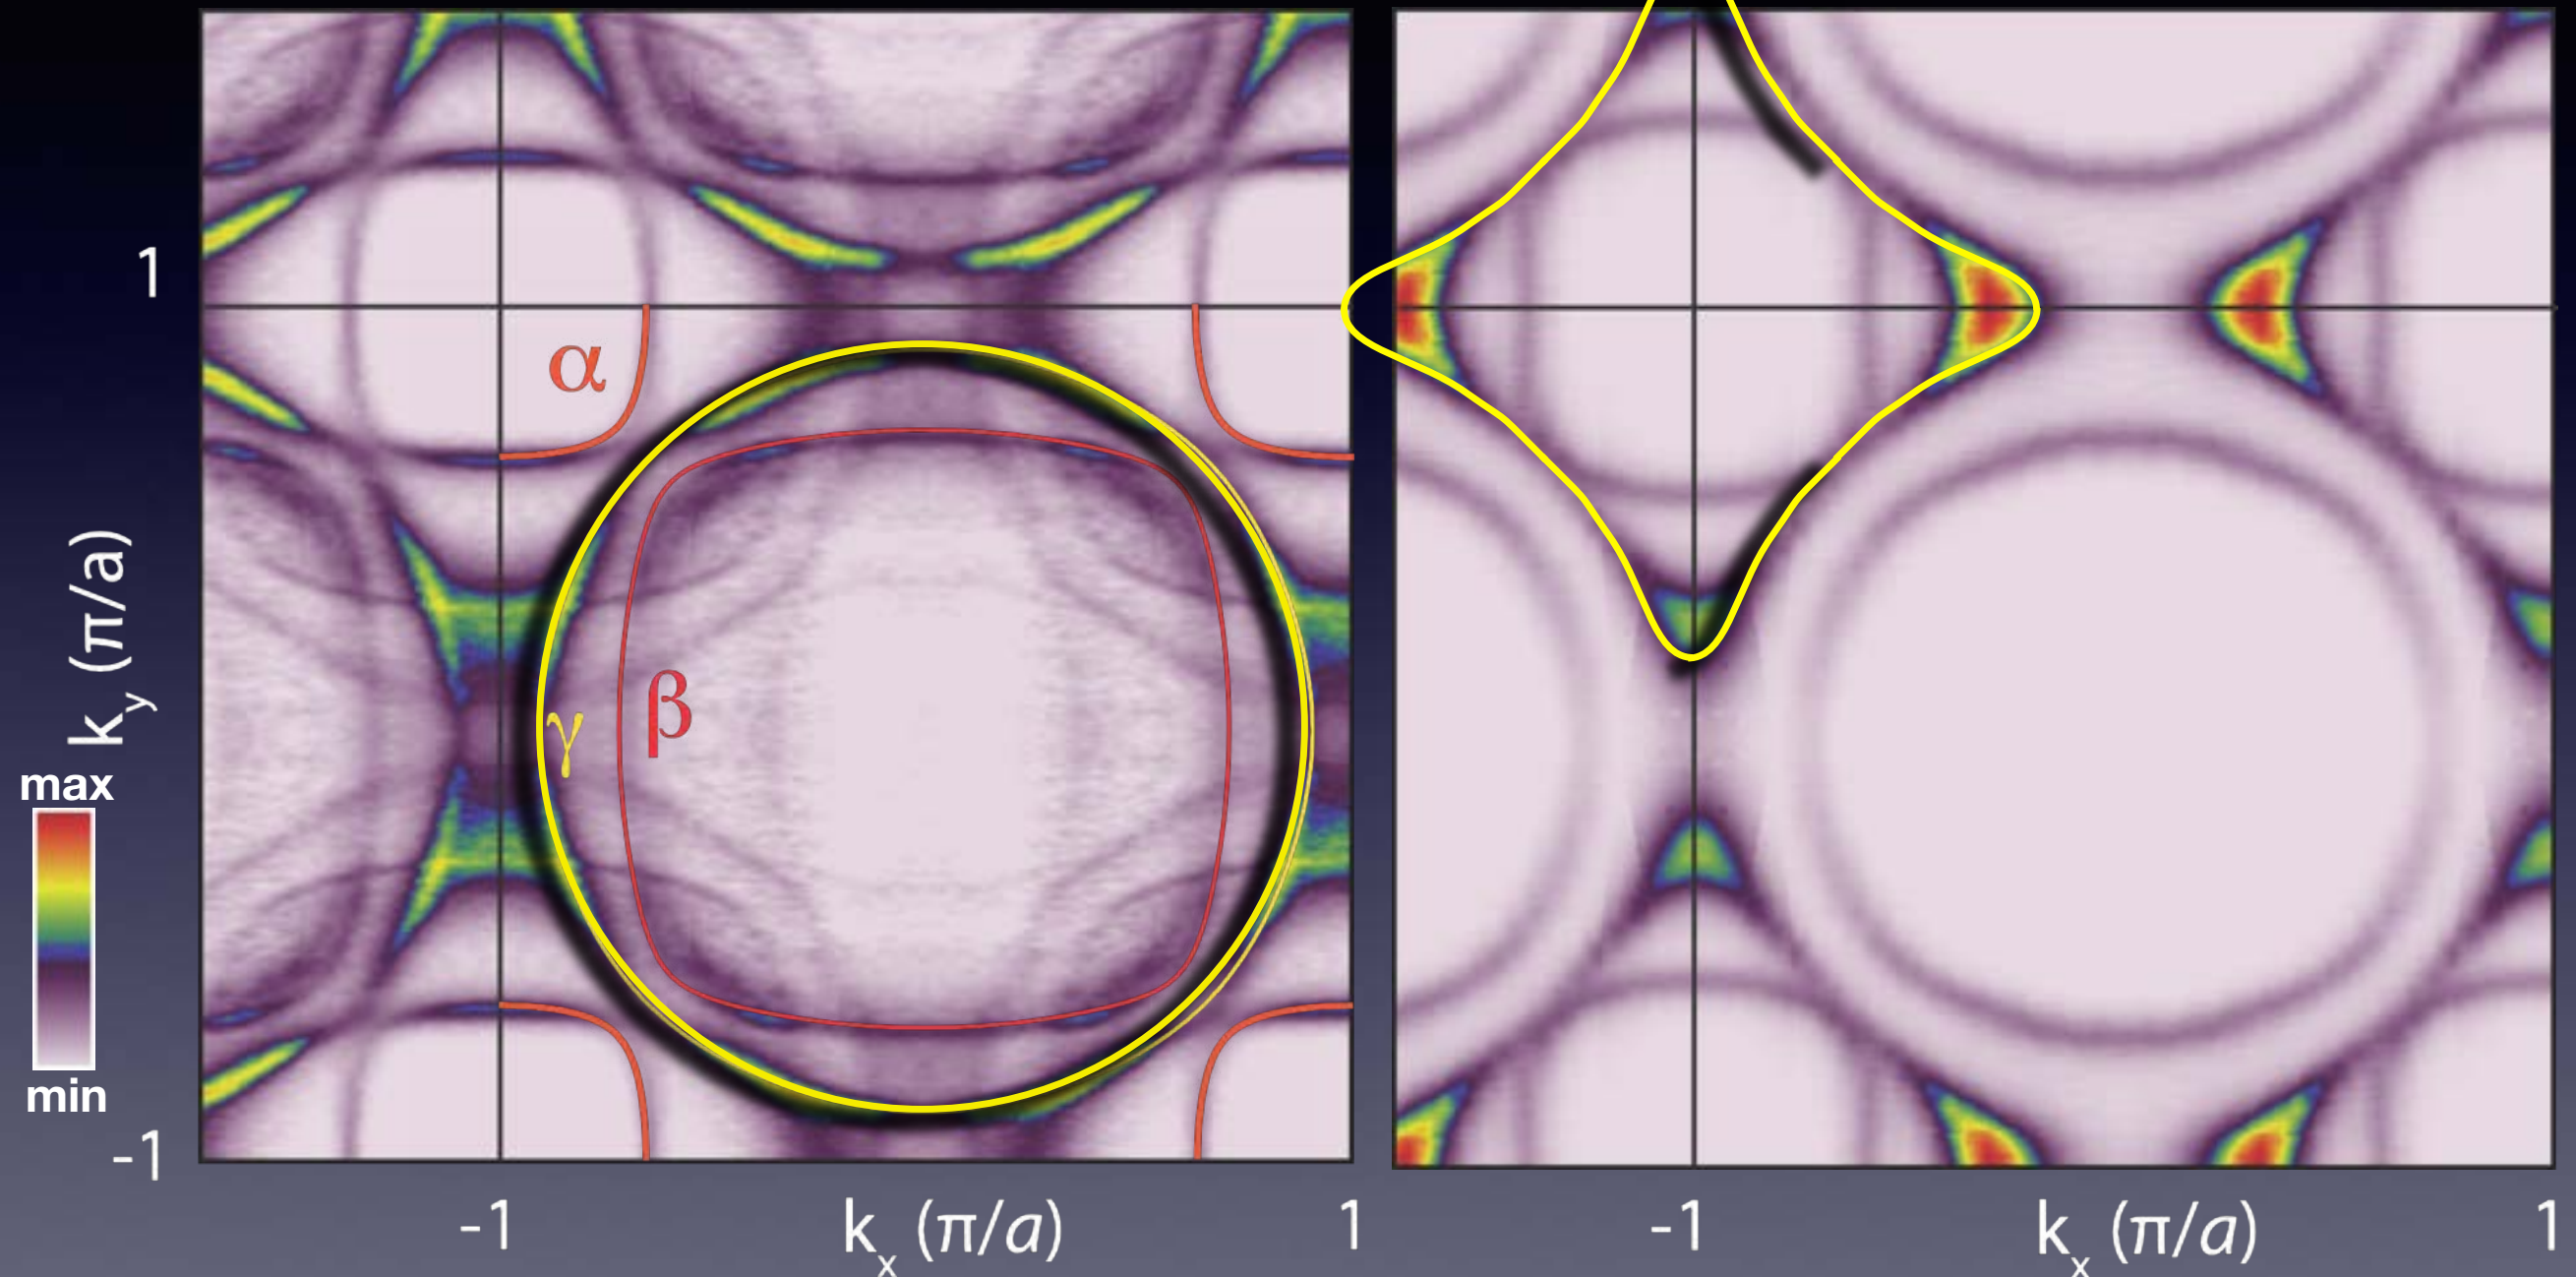

- Ba_2RuO_4 is metastable in bulk but can be epitaxially stabilized

Can tensile strain push the van Hove singularity closer to E_F ?

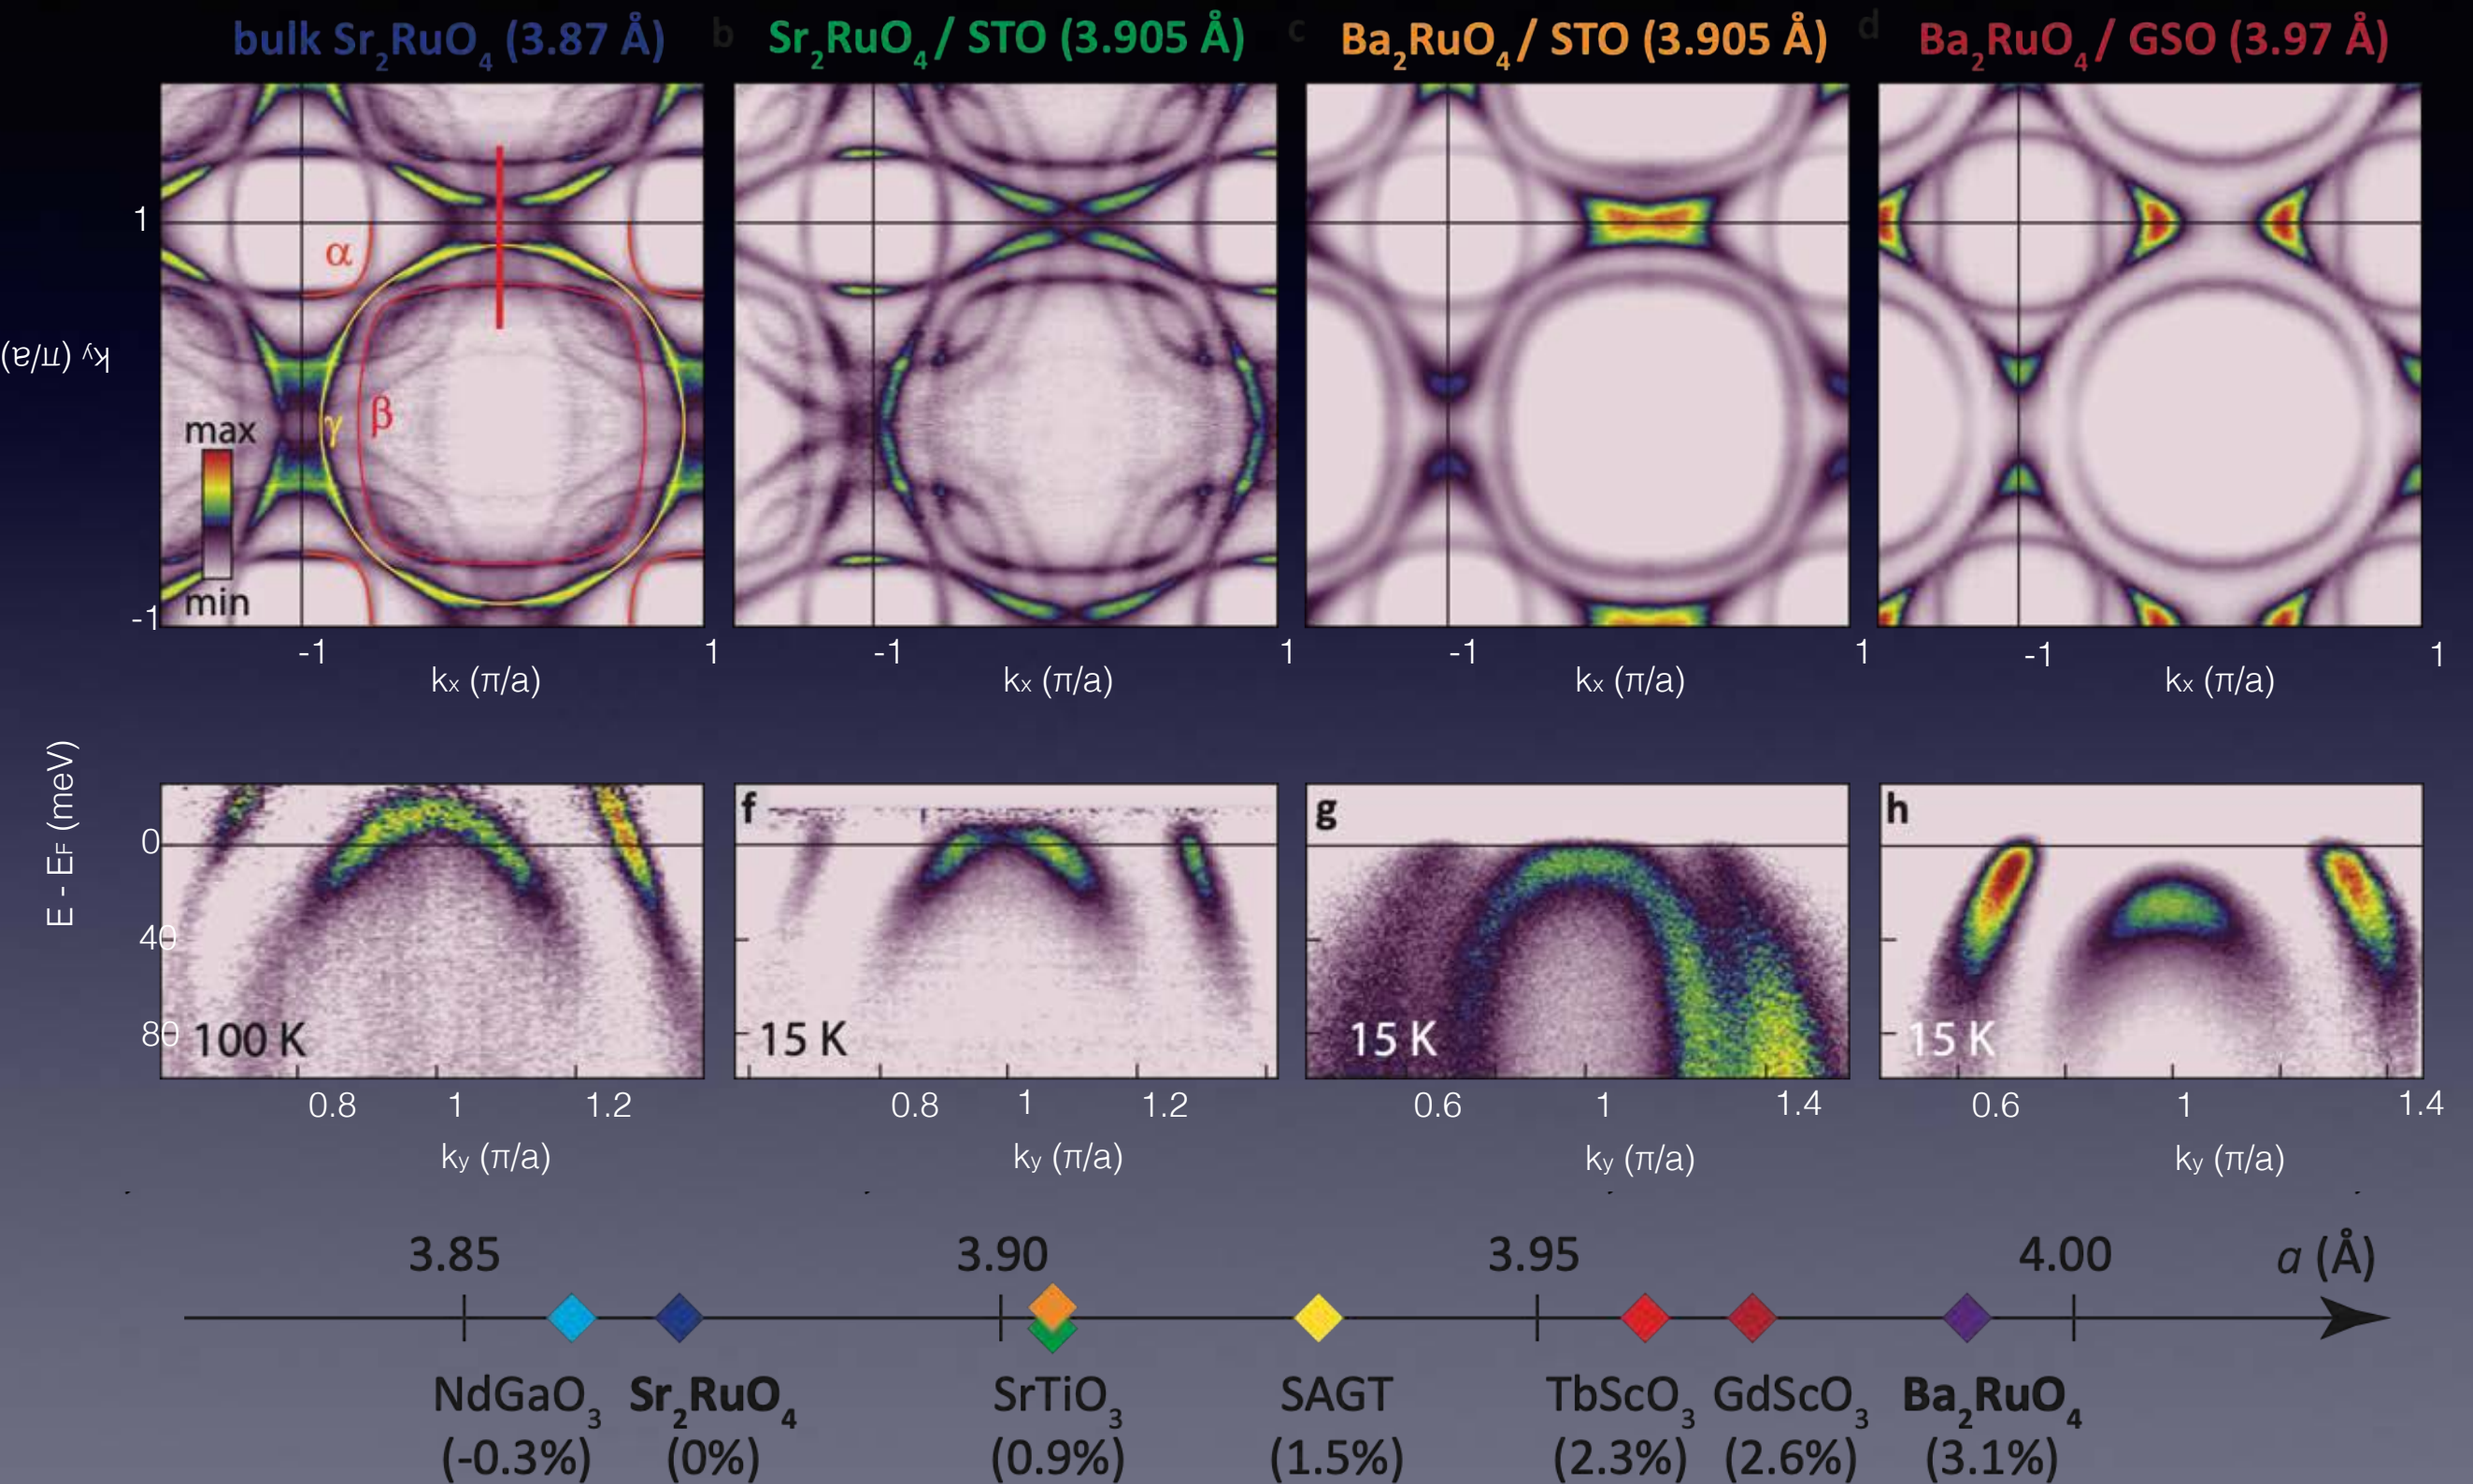

Sr_2RuO_4 single crystal

Ba_2RuO_4 on SrTiO_3 (+0.2%)

low T Hall coefficient changes sign from negative (Sr_2RuO_4) to positive (Ba_2RuO_4), consistent with ARPES

summary of Fermi surface & van Hove singularity evolution with strain

superconductivity depends on orientation of NdGaO₃ substrate
